INF2003 Group project FAQ

Q1. Any language limitations required for building the full stack i.e can we use a mix of Python and SQL.

Yes, you can use a mix of languages.

Q2. Regarding data, shall we only use real life data?

It's all depended on your application. You can directly download data online, crawl from websites or through other resources. If your application requires some user data which is not able to find anywhere, you can synthesis/generate those data.

Q3. If there is any limitation or must do required for the front-end.

Bear in mind that this is a database module, the focus should be on database design and its manipulation. As long as you can demo your application, and the front-end is able to demonstrate the database functions, it is acceptable.

Q4. Are we allowed to use database like Microsoft Access for the relational database?

In theory, you can use Microsoft Access. However, the objective of the group project is to show your competency in database design and data manipulation. Your project should be focused on database design and its application. Choosing certain database software is part of the design process, you should specify why you choose certain database over others: if you choose Access, you need to justify why you opt to this database, is it the best fit for your application? as there's some limitations on Access, and there's other free database options available which are more powerful than Access.

Q5. If diagrams can be included in the appendix section of the progress report, and not counted in the page limit?

Yes, you can include extra diagrams in the appendix in your report, but bear in mind that we may or may not check them during marking.
